1 Introduction

The dataset that I chose is the House Price Prediction dataset, I want to create a model that can effectively predict the price of a house based on its attributes. The dataset I chose gives us a plethora of features to work with. There's a total of 4,600 houses in the data set, each holding the square footage, number of bathrooms, number of bedrooms, how many floors, the condition it is in, the date it was sold, whether or not it has a waterfront and the rating of the view. The benchmark here would be computing the average price of houses, that will be the minimum for a model.
